

How to get Single-Tag Standard Deviation

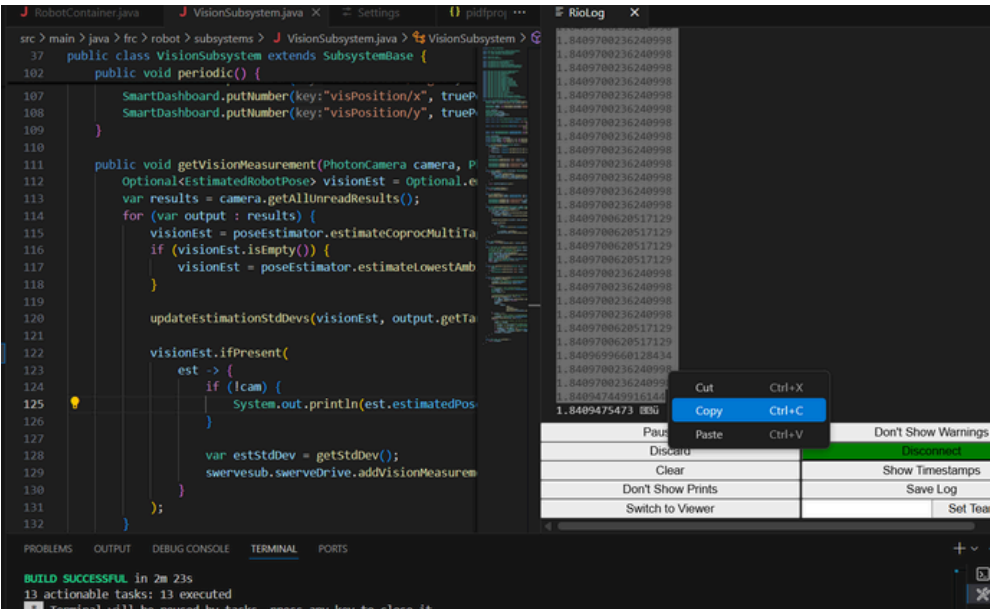

Go to your VisionSubsystem and print out the estimated x-value given by **ONE** of the cameras.

Once you push the code and show an apritag in front of the robot. The RioLog should display the estimated x position of the robot.

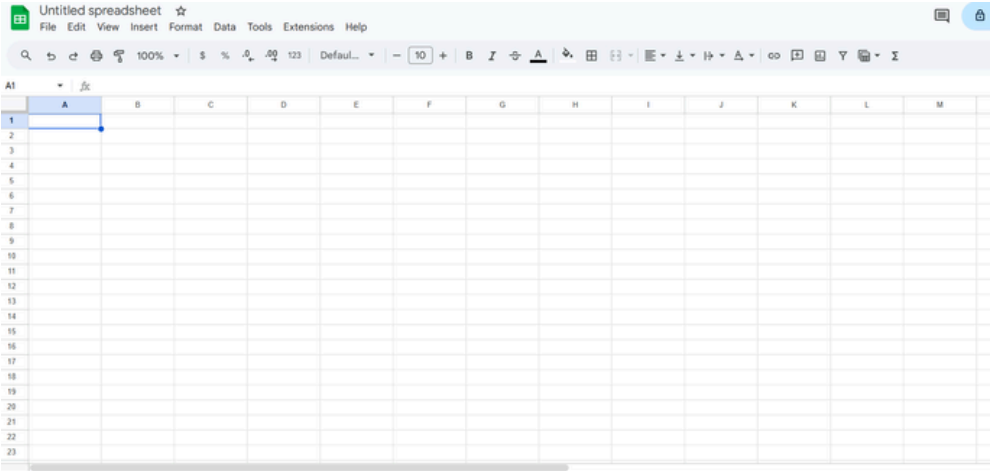

Highlight all the valid x values of the robot (if there is an error message stop there). It is also recommended to pause the RioLog before highlighting the doubles.

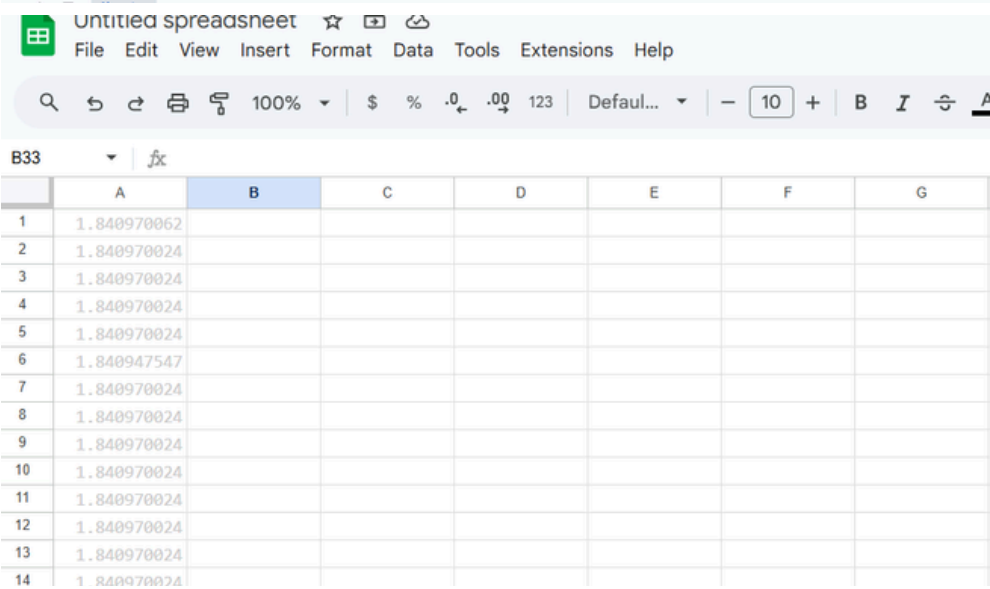

Next right-click and select copy to get each x-value.

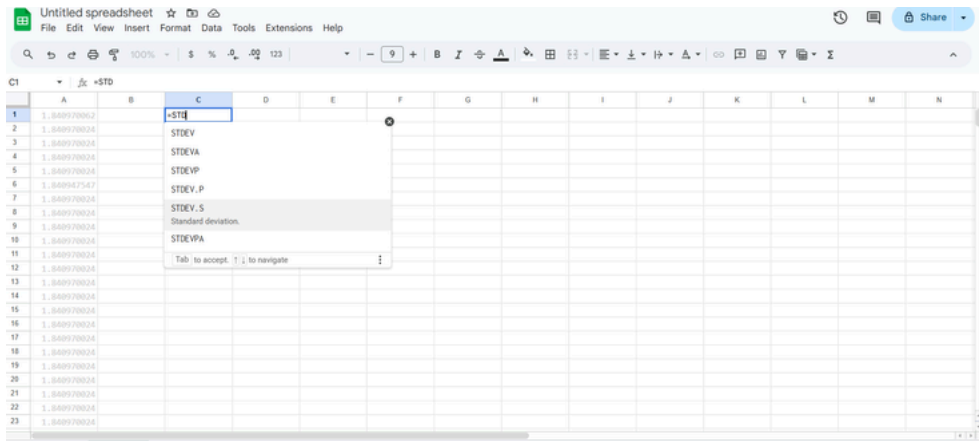

Go onto Google Sheets

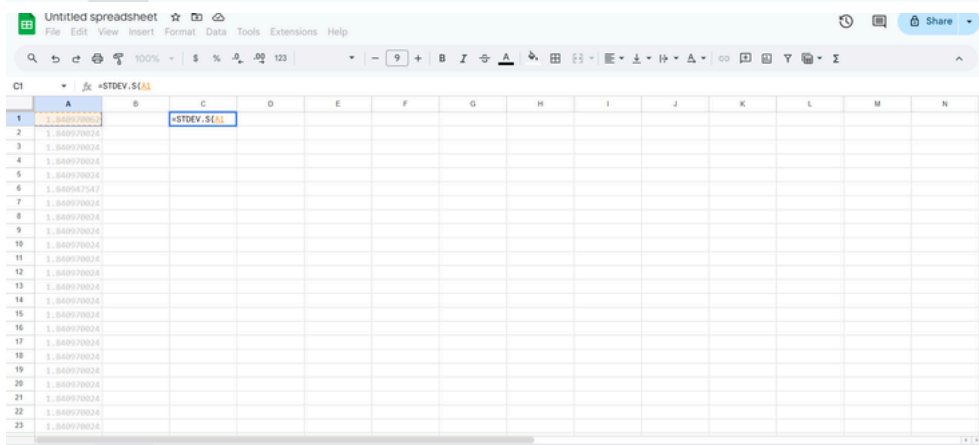

press CNTRL+v on one cell to paste every double onto a different row of the same column.

on a different column, select a cell. type out =STDEV.S as shown to the right.

select the first item at the first row. Then shift click the last item of the last row.

press enter and now you have the standard deviation of that coordinate. Repeat for y and z to get all of the single tag standard deviations.
